Classification of The Types of Geometries

- **Elliptic geometry**
  - Positive curvature
  - Sphere
  - $\Sigma > 180^\circ$
  - $C < \pi$

- **Euclidean geometry**
  - Zero curvature
  - Euclidean plane
  - $\Sigma = 180^\circ$
  - $C = \pi$

- **Hyperbolic geometry**
  - Negative curvature
  - Saddle surface
  - $\Sigma < 180^\circ$
  - $C > \pi$
**Definition: The Upper Half-plane Model**

The upper half-plane \( \mathbb{H} = \{ z \in \mathbb{C} \mid \text{Im}(z) > 0 \} \)
Definition: Hyperbolic Length

Let \( \sigma: [a, b] \to \mathbb{H} \) be a continuously differentiable path in \( \mathbb{H} \). Then the hyperbolic length of \( \sigma \) is obtained by integrating the function \( f(z) = \frac{1}{Im(z)} \) along \( \sigma \), i.e.

\[
\text{length}_{\mathbb{H}}(\sigma) = \int_{\sigma} \frac{1}{Im(z)} = \int_{a}^{b} \frac{|\sigma'(t)|}{Im(\sigma(t))} dt.
\]
Definition: Hyperbolic Distance

Let $z, z' \in \mathbb{H}$. We define the hyperbolic distance $d_{\mathbb{H}}(z, z')$ to be

$$d_{\mathbb{H}}(z, z') = \inf \{ \text{length}_{\mathbb{H}}(\sigma) \mid \sigma \text{ has endpoints } z, z' \}$$

Informally: a geodesic $\sigma$ between $z, z'$ is the length-minimizing path with $z, z'$ as endpoints.
**Geodesics in** $\mathbb{H}$

**Example:** The imaginary axis is a geodesic.

*Proof.* Let $\sigma(t) = it$, $a \leq t \leq b$. Then $\sigma$ is a path from $ia$ to $ib$.

$$length_{\mathbb{H}}(\sigma) = \int_a^b \frac{|\sigma'(t)|}{Im(\sigma(t))} \, dt = \int_a^b \frac{1}{t} \, dt = \ln(b) - \ln(a).$$

Now let $\xi(t) = x(t) + iy(t)$: $[a, b] \to \mathbb{H}$ be any path from $ia$ to $ib$. Then

$$length_{\mathbb{H}}(\xi) = \int_a^b \frac{\sqrt{x'(t)^2 + y'(t)^2}}{y(t)} \, dt \geq \int_a^b \frac{|y'(t)|}{y(t)} \, dt \geq \int_a^b \frac{y'(t)}{y(t)} \, dt = ln(y(t)) \bigg|_a^b = \ln b - \ln a$$

$$= length_{\mathbb{H}}(\sigma).$$
Definition: Möbius Transformations

• Let \(a, b, c, d \in \mathbb{R}\) be such that \(ad - bc > 0\). Define the map \(\gamma: \mathbb{H} \rightarrow \mathbb{H}\) by

\[
\gamma(z) = \frac{az + b}{cz + d}.
\]

• Transformations of \(\mathbb{H}\) of this form are called Möbius transformations of \(\mathbb{H}\).
Application of Möbius Transformations (Pt. 1)

Idea: In our example, we saw that the imaginary axis is a geodesic. We now assert that any vertical line and any circle meeting the real axis orthogonally are geodesics as well. To do this we show that these curves can be mapped to the imaginary axis via Möbius transformations.
Application of Möbius Transformations (Pt. 2)

- Let $L$ be the vertical line $\text{Re}(z) = r$, where $r \in \mathbb{R}$. The translation $z \mapsto z - r$ is a Möbius transformation of $\mathbb{H}$ that maps $L$ to the imaginary axis $\text{Re}(z) = 0$.

- Let $K$ be a semi-circle with the endpoints $t, v \in \mathbb{R}$, where $t < v$. Consider the following map:
  \[ \gamma(z) = \frac{z - v}{z - t}. \]

- Since $-t + v > 0$, this is a Möbius transformation of $\mathbb{H}$. $\gamma(v) = 0$ and $\gamma(t) = \infty$, and we have thus mapped $K$ to the imaginary axis $\text{Re}(z) = 0$.
